The Hawaii Forestry and Communities Initiative
The Division of Forestry and Wildlife**

Executive summary:

In 1998, a comprehensive inventory of non-native timber resources was conducted within the Puu Ka Pele, Na Pali-Kona, and Lihue-Koloa Forest Reserves on the island of Kauai. Primary survey objectives included producing accurate forest type maps, estimating marketable wood volume, and assessing the extent of timber losses sustained due to hurricane damage.

Mapping efforts revealed that non-native timber resources on Kauai were comprised of 178 timber stands in 25 forest types, occupying approximately 2,190 acres in Forest Reserves, and 200 acres within State Parks and other areas. Forest sampling was conducted by random sampling of fixed radius plots in selected stands.

The sum of volume in all forest types exceeded 4,300,000 net cubic feet, or approximately 21,500,000 net board feet assuming a conversion factor of five board feet per cubic foot. The survey intensity and resulting volume analyses of this study were designed to provide guidelines for long-term forest management, and were not intended to be the sole basis for conducting timber sales.

Eucalyptus saligna and *E. microcorys* appeared to be well suited to the growing conditions found in Western Kauai, with mean annual increment (MAI) values ranging between 150-300 gross ft³ acre⁻¹ year⁻¹. *E. robusta*, Southern pines, and other minor species have not grown as well in their current locations, with mean annual increments typically ranging between 30-90 gross ft³ acre⁻¹ year⁻¹. Hurricane damage was negligible in Southern Pine stands, whereas stands of Eucalyptus and related species sustained heavy damage.

Introduction:

From July to September 1998, The Hawaii Forestry and Communities Initiative (HFCI) timber survey crew conducted an inventory of publicly held non-native timber resources on Kauai. The primary objectives of the inventory were to provide:

1. Accurate forest type maps.
2. Volume estimates of commercial timber resources.
3. An assessment of timber losses sustained due to hurricane damage.

A majority of the surveyed timber resources were located on lands managed by the Division of Forestry and Wildlife (DOFAW). The primary concentration of DOFAW-managed non-native timber was located within Puu Ka Pele Forest Reserve, west of State Route 550 (Kokee Road). Most of the remaining timber acreage was located in adjacent stands that exist within Na Pali-Kona Forest Reserve and Waimea Canyon State Park. Hereafter, the geographic area containing timber stands from these areas is referred to as the West Kauai survey area. The remaining timber stands were located west of Wailua in the Lihue-Koloa Forest Reserve, hereafter referred to as the East Kauai survey area.

The first comprehensive inventory of plantation timber on Kauai reported merchantable wood volume of approximately 2,000,000 cubic feet on State lands (Honda et al., 1967). A second survey of plantations that were established after 1960, or had tree diameters ranging from 5-11" in the 1967 report, assessed smaller trees as a biomass resource (Division of Forestry, 1979). The latter survey revealed more than 3,500,000 gross cubic feet of plantation timber volume on Kauai in what were then relatively young timber stands.

Non-native timber stands in the West Kauai survey area were located primarily on ridge tops having an east-west orientation, and within an elevation range of 1000-3500 feet. Average annual rainfall on these ridge tops ranges from approximately 30-55 inches, with rainfall positively correlated to elevation. Most soils in the area are ash-derived silty loams from the Mahana and Oli Series, or basalt-derived clay loams from the Niu and Puu Opae Series (Soil Conservation Service, 1972). These soils are classified as well drained.

The structure of vegetation communities in the West Kauai survey area approximated Lowland Mesic Shrublands and Lowland Mesic Forests (Wagner et al., 1990). Excluding planted non-native species, overstory trees included koa (*Acacia koa*) and ohia (*Metrosideros polymorpha*). Aalii (*Dodonaea viscosa*), pukiawe (*Styphelia tameiameiae*), uluhe (*Dicranopteris linearis*), *Lantana camara*, guava (*Psidium* spp.), molasses grass (*Melinis minutiflora*), and ukiuki (*Dianella sandwicensis*) are common understory and groundcover species.

Non-native timber stands in the East Kauai survey area were located in undulating terrain within an elevation range of 700-1000 feet. Average annual rainfall ranges from approximately 100-155 inches. Most soils in the area are alluvial silty clays in the Hanalei and Hanamaulu Series', or basalt-derived silty clays of the Pooku Series (Soil Conservation Service, 1972). These soils are classified as poorly drained to well drained depending on local topography.

The vegetation community in the East Kauai survey area is a diverse mosaic dominated by alien species. Excluding planted non-native species, overstory trees included Molucca albizia (*Paraserianthes falcataria*) and remnant ohia. Guava, *Melastoma* spp., and various ferns were common understory and groundcover species.

Survey methodology:

Planting maps, harvest maps, satellite imagery and aerial photographs were used to develop initial timber stand boundaries. During field inventory work, the survey crew verified and updated these boundaries while concurrently assigning forest types to each stand based on primary timber species, age, and stand composition.

A survey plot grid was created for the island of Kauai with one point for every five acres. Plot sampling was concentrated in stands of commercially important species, and in larger stands to facilitate sampling efficiency (72% of all stands were smaller than 15 acres).

Circular sample plots were 0.10 acres in size, with a fixed radius of 37.24 feet. All tree species larger than 5.5" diameter at breast height (DBH) were measured as "main plot" trees. Each plot tree was numbered and measured for DBH. Total height and defect assessments were recorded for every fifth tree of each species encountered on the plot. Defects were visually estimated and recorded as a percentage deduction of wood volume for the bottom-, middle-, and top-third of the tree. Regeneration data were recorded by tallying all tree stems in a DBH range of 1.6-5.5" within a nested 0.05 acre (26.33 feet in radius) "sub-plot."

Three primary overstory, understory, and groundcover species on or near each plot point were recorded in order of decreasing abundance. These data did not represent actual stem counts. Other descriptive data collection included slope, aspect, and weather conditions.

Survey data were analyzed using Forestry Projection System software version 5.3a (Forest Biometrics, 1998). Gross wood volume calculations represented volume from tree base to tree tip. Merchantable wood volume calculations were based on 16 foot log sections, a minimum top diameter of four inches, a stump height of one foot, and a minimum DBH of eight inches. Net wood volume calculations were based on merchantable wood volume minus deductions due to tree defects. Defect percentages were calculated using the formula:

$$\text{Defect (\%)} = (V_m - V_n / V_m), \text{ where } V_m = \text{merchantable volume, and } V_n = \text{net volume.}$$

Once the initial survey was completed, all stand acreage and plot data were post-stratified by forest type. Acreage from unique or very small stands that had not been sampled were assigned to the forest type which best approximated their stand structure. Volume calculations were based on data from all cruised stands within each forest type. These data were subsequently used to predict volume in non-cruised stands of the same type. Though certain species are currently considered non-merchantable (Appendix A) due to either poor quality or availability, they are included in volume summaries.

Only one local taper profile was available for volume analyses of species encountered during this survey, necessitating the use of taper profiles from alternate species and regions (Appendix B).

Survey results:

The 1998 timber plantation map contains 178 timber stands totaling 2,386 acres, excluding clearings (Figures 1a & 1b). Total wood volume in 1998 exceeded 4,300,000 net cubic feet (Table 1). All mapped stands were stratified into 25 unique forest types based on dominant overstory tree species, age and stand structure, allowing type-level volume summaries (Table 2). Additional detail for type-level volume data are presented in Appendix C. Approximately 56% of net wood volume occurred on only 34% of the surveyed acreage (forest type codes of "33" or higher). These stands contained a high proportion of total volume due to relatively high tree stocking and large tree size. The remaining 44% of net wood volume occurred on 66% of the surveyed acreage (forest type codes of "22" or lower). The latter forest types included stands that had poor survival or growth, were poorly stocked, were recently planted,

or had sustained considerable hurricane damage. If the entire inventory of surveyed trees were harvested at once and cut into sixteen foot logs, wood volume in log diameter classes of 4-8", 8-12", and 12+" would equal 1,802,376, 1,443,376, 1,105,710 net cubic feet, respectively (41%, 33%, and 26% of the total net volume, respectively).

Volume results expressed in units of mean cubic feet per acre were derived from statistical sampling, and are therefore estimates. Standard error (SE) analyses provide one tool for assessing the strength of the field survey data. In the sampled forest types, standard error values rarely exceeded 20 percent of the mean (Table 3). Confidence intervals associated with standard error estimates represent the range of net volume per acre that is 80% likely to contain the true mean volume per acre for each forest type.

While individual stands were assigned to forest types based on the dominant overstory species, type level volume data also included components of secondary species (Table 4). Most forest types had only one or two principal species components.

Within the non-native timber plantations, few ohia and koa trees were left standing during initial land clearing operations. As a result of this practice, non-native species comprised

Table 2. Descriptive statistics for timber types in the Kauai timber survey. Age data represent original planting date, while stocking and DBH data represent all tree species with a minimum DBH of 2 inches. Maximum DBH data represent planted, non-native trees only.

100% of the primary overstory species recorded at sample plots. Koa, and to a lesser extent ohia, were observed as secondary overstory species at 6% and 1% of all sampled plot points, respectively.

Other tree species observed and measured in minor quantities during the survey, included Formosa koa (*Acacia confusa*), silk oak (*Grevillea robusta*), Monterey pine (*Pinus radiata*), and ironwood (*Casuarina equisetifolia*). No detailed volume or distribution analyses were conducted for these species due to their scattered occurrence.

Silk oak was the most common and widely distributed secondary overstory species within the West Kauai study area, while other species were found in localized concentrations (Figure 2a). Molucca albizia (*Paraserianthes falcataria*) was clearly the most common secondary overstory species in the East Kauai study area, indicating that this species can rapidly spread and colonize disturbed sites (Figure 2b). Molucca albizia was notably absent in stands of paperbark (*Melaleuca quinquenervia*), which were well established when albizia first colonized the area.

Relative abundance data for understory species revealed that guava is common throughout the West Kauai study area (Figure 3a). This species appears to be highly shade tolerant as it was commonly found under well-stocked and mature stands of timber. Other commonly recorded understory species were tree seedlings found under parent trees of the same species. In the East Kauai survey area, *Melastoma* spp., guava, and Molucca albizia dominated the forest understory (Figure 3b).

Alien species were most common in the groundcover layer of the West Kauai study area (Figure 4a). Both *Lantana camara* and molasses grass (*Melinis minutiflora*) were widespread, though the latter occurred almost exclusively under a pine overstory. Though less common, the native species pukiawe and ukiuki also had a wide distribution in West Kauai. Various ferns and guava were the primary components of the groundcover layer in the East Kauai study area (Figure 4b).

Discussion and planning implications:

The non-native timber plantings on Kauai exhibited a wide range of growth potential both within, and among species. Site adaptation and climatic conditions appeared to be the primary factors that influenced stand growth potential. Current within-species productivity differences can not be attributed to varying stand management or maintenance, since little has been conducted historically.

In order to compare productivity of different species, representative stands within the most important commercial forest types were selected for mean annual increment (MAI) analyses (Table 5). Among the non-native plantation species, MAI values were highest for the eucalypts, commonly ranging from $150\text{-}300 \text{ ft}^3 \text{ ac}^{-1} \text{ yr}^{-1}$. One exception was *Eucalyptus robusta*, for which MAI did not exceed $80 \text{ ft}^3 \text{ ac}^{-1} \text{ yr}^{-1}$ in any stand. At elevations above 2400

feet in the West Kauai study area, southern pines had MAI values approaching, and sometimes exceeding $100 \text{ ft}^3 \text{ ac}^{-1} \text{ yr}^{-1}$. MAI values for all other species and southern pines below 2400 feet were very low.

Low MAI values for *E. robusta* may be misleading for some stands because they were the oldest within the study area, and may have stagnated. Other stands are clearly stunted in growth, indicating that *E. robusta* is not suited to site conditions in its current planting range. *E. robusta* grows well in a wide range of other soil-elevation combinations statewide, so long as annual rainfall is high. The relatively dry climate within the West Kauai study area is probably the primary factor for poor performance of *E. robusta*. Though less pronounced than in *E. robusta*, inhibited growth of other eucalypts and the southern pines is apparent at the drier low elevation areas of the West Kauai Study area. Productivity for several of the timber species studied would probably increase significantly with intensified stand management and modified species-site selections in future rotations.

Some MAI values for stands in the same forest type were very different (Table 5). It is important to note that MAI calculations were conducted on a gross volume basis, while stands were assigned to forest types based on current stand structure and net volume. Many trees that had broken tops as the result of hurricane damage are still living. Gross volume (and MAI) calculations for these trees include theoretical volume above the break point to an estimated former height, while net volume calculations do not.

Defect deductions attributed to form and rot versus hurricane damage were not quantitatively separated during the survey. However, field observations from the survey crews indicated that a vast majority of deductions were associated with hurricane damage. Analyses of defect deductions revealed high levels of hurricane damage for all timber types with the exception of southern pines (Table 6). The southern pines proved to be most resistant to wind damage, suffering minor defects ranging from 2% to 5%. The eucalypts were heavily impacted, with most species sustaining volume losses of 20% or more. The single stand of surveyed brushbox (*Lophostemon confertus*) sustained the heaviest hurricane damage with a volume loss of 57%. Of the nearly four thousand trees measured during this survey, approximately 25% had broken tops associated with hurricane damage (Table 7). Species level analyses of percentage of trees with broken tops paralleled the defect deductions discussed above.

Qualitative data collection for the relative abundance of primary and secondary species in the study areas revealed a predominance of non-native timbers, underlain by invasive non-native weed species. If current commercial timber resources are harvested, control of these weed species will probably require significant resources during planting and establishment of future timber plantations.

Total wood volume estimates for surveyed non-native timber resources exceeded 4,300,000 net cubic feet, or approximately 21,500,000 net board feet. Forest types coded “22” or lower could be considered to represent pre- or non-commercial timber acreage as of 1998 due to their low volume or heterogeneous composition. Well-stocked stands in these forest types

Table 6. Defect analyses for forest types measured during the Kauai timber survey.

Species & Type Description	--Mean ft³ ac⁻¹--			% Defect
	Merch	Net		
Eucalyptus robusta				
ER00 Recent plantings / sapling stands	1,081	884		18

could have significant commercial value in future years, while others will have salvage potential at best unless they are replaced. Forest types coded “33” or higher contained a majority of timber resources with current commercial value, where total net volume exceeded 2,400,000 cubic feet, or approximately 12,000,000 board feet.

Table 7. Analyses of plot trees with broken tops. Occurrence of broken tops can almost exclusively be attributed to hurricane damage.

Species	-----Trees-----		
	Total	Broken	% Broken
Eucalyptus robusta	991	360	36
Eucalyptus saligna	838	244	29
Eucalyptus sideroxylon	39	4	10
Eucalyptus microcorys	314	147	47
Eucalyptus paniculata	79	20	25
Lophostemon confertus	59	58	98
Melaleuca quinquenervia	143	46	32
Pinus elliottii	759	10	1
Pinus taeda	328	16	5
Acacia koa	89	2	2
Grevillea robusta	109	33	30
Paraserianthes falcataria	144	21	15
Total	3,892	961	25

The surveyed timber stands represent a readily accessible resource due to comprehensive road networks, which would facilitate implementation of intensive forest management activities. Though some roads have become overgrown, they could be easily cleared prior to future operations. However, slopes exceeding 25% are common in the West Kauai study area, so operation of vehicles and heavy equipment would be restricted by slick road conditions during rainy periods.

Analyses of survey precision indicated that reported timber volumes were moderately robust. Hurricane damage caused considerable heterogeneity in stand structure, and the current commercial value of many stands will be dependent on the extent to which successful salvage and replacement operations can be implemented.

Minor acreage of non-native timber stands included in the scope of this study fall under the management or ownership of organizations other than DOFAW (Appendix D).

The volume data in this report are not intended to be the sole basis for negotiation of timber sale contracts, but rather a guideline to long term timber management planning within the surveyed areas. Careful weighing or scaling of timber removed from harvest sites is highly recommended for all harvest contracts.

Acknowledgements:

We thank Jim Thain, Fetu Amuimuia, Ron Miyashiro, Paul Camba, and Kamakani Dancil of the HFCI timber inventory crew for conducting the field survey. The Kauai Branch of the Department of Land and Natural Resources, Division of Forestry and Wildlife provided invaluable logistical support for the crew during the Kauai survey. This project was conducted by the Hawaii Forestry and Communities Initiative and its supporting agencies. Funding was provided by the USDA Forest Service Economic Recovery Program, and the Department of Land and Natural Resources, Division of Forestry and Wildlife.

TREE SPECIES

<u>Latin genus and species</u>	<u>Common name</u>
<i>Acacia confusa</i>	Formosa koa
<i>Acacia koa</i>	Koa
<i>Acacia mearnsii</i>	Black wattle
<i>Aleurites moluccana</i>	Kukui
<i>Casuarina equisetifolia</i>	Ironwood
<i>Eucalyptus deglupta</i>	Mindanao Gum
<i>Eucalyptus paniculata</i>	Grey Ironbark
<i>Eucalyptus microcorys</i>	Tallow-wood
<i>Eucalyptus robusta</i>	Swamp mahogany
<i>Eucalyptus saligna</i>	Sydney blue gum
<i>Eucalyptus sideroxylon</i>	Red Ironbark
<i>Grevillea robusta</i>	Silk oak
<i>Leucaena leucocephala</i>	Koa-haole
<i>Lophostemon confertus</i>	Brushbox
<i>Melaleuca quinquenervia</i>	Paper bark
<i>Metrosideros polymorpha</i>	Ohia
<i>Myrica Faya</i>	Firetree
<i>Paraserianthes falcataria</i>	Molucca Albizia
<i>Pinus elliottii</i>	Slash pine
<i>Pinus radiata</i>	Monterey pine
<i>Pinus taeda</i>	Loblolly pine
<i>Schinus terebinthifolius</i>	Christmas berry

UNDERSTORY AND GROUNDCOVER SPECIES

<u>Latin genus and species</u>	<u>Common name</u>
<i>Dianella sandwicensis</i>	Ukiuki
<i>Dicranopteris linearis</i>	Uluhe fern
<i>Dodonaea viscosa</i>	Aalii
<i>Freycinetia arborea</i>	Ieie
<i>Lantana camara</i>	Lantana
<i>Melastoma</i> spp.	Melastoma family
<i>Melinis minutiflora</i>	Molasses grass
<i>Nephrolepis multiflora</i>	Sword fern
<i>Psidium</i> spp.	Guava
<i>Styphelia tameiameiae</i>	Pukiawe

Appendix B. Species assignments by taper profile class for volume analyses.

Species analyzed using a Hawaiian *Flindersia brayleyana* taper profile:

1. *Acacia confusa*
2. *Acacia koa*
3. *Acacia mearnsii*
4. *Aleurites moluccana*
5. *Casuarina equisetifolia*
6. *Grevillea robusta*
7. *Leucaena leucocephala*
8. *Metrosideros polymorpha*
9. *Myrica faya*
10. *Paraserianthes falcataria*
11. *Schinus terebinthifolius*

Species analyzed using a Hawaiian *Eucalyptus saligna* taper profile:

1. *Eucalyptus microcorys* (bark thickness coefficients 1.5 times those of *E. saligna*)
2. *E. paniculata* (bark thickness coefficients 1.5 times those of *E. saligna*)
3. *E. robusta* (bark thickness coefficients 2.0 times those of *E. saligna*)
4. *E. saligna*
5. *E. sideroxylon* (bark thickness coefficients 1.5 times those of *E. saligna*)
6. *Lophostemon confertus*
7. *Melaleuca quinquenervia* (bark thickness coefficients 2.0 times those of *E. saligna*)

Species analyzed using a Hawaiian *Eucalyptus grandis* taper profile:

1. *Eucalyptus deglupta*

Species analyzed using a Pacific Northwest *Pinus contorta* (lodgepole pine) taper profile:

1. *Pinus elliottii*
2. *Pinus taeda*

Appendix C. Stand tables by forest type.

Guidelines for interpreting stand table data:

1. Stand tables summarize sample plot analyses using one-inch DBH classes. Statistics provided for each DBH class include trees per acre, basal area per acre (ft^2), average tree height (feet), and cubic foot volume per acre. Gross cubic volume represents the tree bole from tree base to tree tip. Merchantable wood volume calculations were based on 16 foot log sections, a minimum top diameter of four inches, a stump height of one foot, and a minimum DBH of eight inches. Net wood volume represents merchantable volume minus deductions due to tree defects.
2. For each forest type, statistics are first presented by tree species. The last row of each species section gives a species summary (species codes typically use the first initial from both genus and species names). The species summary shows average DBH, total trees per acre, total basal area per acre, and total volume per acre.
3. After all species for a particular forest type have been listed, two final rows provide type level summary statistics. The first row represents all trees with a DBH of two inches or larger. The second row represents only trees with a minimum DBH of eight inches. Type level summaries show average DBH, total trees per acre, total basal area per acre, and total volume per acre. Type level volume totals may differ slightly from those reported in Tables 2-4 & 6 due to rounding errors.
